Quantium Virtual Internship - Retail Strategy and Analytics - Task

Iman Hamza

Solution template for Task 2

This file is a solution template for the Task 2 of the Quantium Virtual Internship. It will walk you through the analysis, providing the scaffolding for your solution with gaps left for you to fill in yourself. Look for comments that say "over to you" for places where you need to add your own code! Often, there will be hints about what to do or what function to use in the text leading up to a code block - if you need a bit of extra help on how to use a function, the internet has many excellent resources on R coding, which you can find using your favourite search engine. ## Load required libraries and datasets Note that you will need to install these libraries if you have never used these before.

Point the filePath to where you have downloaded the datasets to and

```
# Over to you! Fill in the path to your working directory. If you are on a
# Windows machine, you will need to use forward slashes (/) instead of back
# hashes (\) file Path <- ''
data <- fread(pasteO("QVI_data.csv"))
#### Set themes for plots
theme_set(theme_bw())
theme_update(plot.title = element_text(hjust = 0.5))</pre>
```

assign the data files to data.tables

Select control stores

The client has selected store numbers 77, 86 and 88 as trial stores and want control stores to be established stores that are operational for the entire observation period. We would want to match trial stores to control stores that are similar to the trial tore prior to the trial period of Feb 2019 in terms of: - Monthly overall sales revenue - Monthly number of customers - Monthly number of transactions per customer Let's first create the metrics of interest and filter to stores that are present throughout the pre-trial period.

```
#### Calculate these measures over time for each store Over to you! Add a new
#### month ID column in the data with the format yyyymm. monthYear <-
#### format(as.Date(data$DATE, '%Y%m'))
data[, `:=`(YEARMONTH, year(DATE) * 100 + month(DATE))]
#### Next, we define the measure calculations to use during the analysis. Over
#### to you! For each store and month calculate total sales, number of
##### customers, transactions per customer, chips per customer and the average</pre>
```

Now we need to work out a way of ranking how similar each potential control store is to the trial store. We can calculate how correlated the performance of each store is to the trial store. Let's write a function for this so that we don't have to calculate this for each trial store and control store pair.

```
#### Create a function to calculate correlation for a measure, looping through
#### each control store. Let's define inputTable as a metric table with
#### potential comparison stores, metricCol as the store metric used to
#### calculate correlation on, and store Comparison as the store number of the
#### trial store.
calculateCorrelation <- function(inputTable, metricCol, storeComparison) {</pre>
    calcCorrTable = data.table(Store1 = numeric(), Store2 = numeric(),
        corr measure = numeric())
    storeNumbers <- unique(inputTable[, STORE NBR])</pre>
   for (i in storeNumbers) {
        calculatedMeasure = data.table(Store1 = storeComparison, Store2 = i,
            corr_measure = cor(inputTable[STORE_NBR == storeComparison,
                eval(metricCol)], inputTable[STORE_NBR == i, eval(metricCol)]))
        calcCorrTable <- rbind(calcCorrTable, calculatedMeasure)</pre>
   }
   return(calcCorrTable)
```

Apart from correlation, we can also calculate a standardised metric based on the absolute difference between the trial store's performance and each control store's performance. Let's write a function for this.

```
measure = abs(inputTable[STORE_NBR ==
                storeComparison, eval(metricCol)] -
                inputTable[STORE_NBR == i, eval(metricCol)]))
        calcDistTable <- rbind(calcDistTable,</pre>
            calculatedMeasure)
    }
    #### Standardize the magnitude distance so that the measure ranges from 0
    minMaxDist <- calcDistTable[, .(minDist = min(measure),</pre>
        maxDist = max(measure)), by = c("Store1",
        "YEARMONTH")]
    distTable <- merge(calcDistTable, minMaxDist,</pre>
        by = c("Store1", "YEARMONTH"))
    distTable[, `:=`(magnitudeMeasure, 1 - (measure -
        minDist)/(maxDist - minDist))]
    finalDistTable <- distTable[, .(mag_measure = mean(magnitudeMeasure)),</pre>
        by = .(Store1, Store2)]
    return(finalDistTable)
}
```

Now let's use the functions to find the control stores! We'll select control stores based on how similar monthly total sales in dollar amounts and monthly number of customers are to the trial stores. So we will need to use our functions to get four scores, two for each of total sales and total customers.

```

            77
                         -0.7856990
#### Then, use the functions for calculating magnitude.
magnitude_nSales <- calculateMagnitudeDistance(preTrialMeasures,</pre>
    quote(totSales), trial_store)
magnitude_nCustomers <- calculateMagnitudeDistance(preTrialMeasures,</pre>
    quote(nCustomers), trial_store)
```

We'll need to combine the all the scores calculated using our function to create a composite score to rank on. Let's take a simple average of the correlation and magnitude scores for each driver. Note that if we consider it more important for the trend of the drivers to be similar, we can increase the weight of the correlation score (a simple average gives a weight of 0.5 to the corr_weight) or if we consider the absolute size of the drivers to be more important, we can lower the weight of the correlation score.

```

Now we have a score for each of total number of sales and number of customers. Let's combine the two via a simple average.

The store with the highest score is then selected as the control store since it is most similar to the trial store.

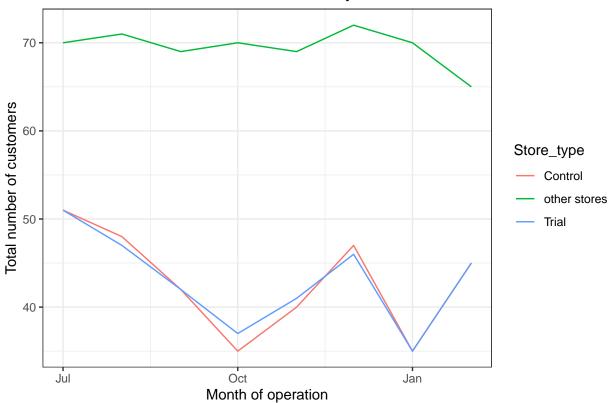

[1] 233

Now that we have found a control store, let's check visually if the drivers are indeed similar in the period before the trial. We'll look at total sales first.

Next, number of customers.

Assessment of trial The trial period goes from the start of February 2019 to April 2019. We now want to see if there has been an uplift in overall chip sales. We'll start with scaling the control store's sales to a level similar to control for any differences between the two stores outside of the trial period.

Now that we have comparable sales figures for the control store, we can calculate the percentage difference between the scaled control sales and the trial store's sales during the trial period.

```
#### Over to you! Calculate the percentage difference between scaled control
#### sales and trial sales
percentageDiff <- merge(scaledControlSales[, c("YEARMONTH", "controlSales")],
    measureOverTime[STORE_NBR == trial_store, c("YEARMONTH", "totSales")],
    by = "YEARMONTH")[, `:=`(percentageDiff, abs(controlSales -
    totSales)/controlSales)]</pre>
```

Let's see if the difference is significant!

```
#### As our null hypothesis is that the trial period is the same as the
#### pre-trial period, let's take the standard deviation based on the scaled
#### percentage difference in the pre-trial period
stdDev <- sd(percentageDiff[YEARMONTH < 201902, percentageDiff])
#### Note that there are 8 months in the pre-trial period hence 8 - 1 = 7
#### degrees of freedom
degreesOfFreedom <- 7
#### We will test with a null hypothesis of there being 0 difference between
#### trial and control stores. Over to you! Calculate the t-values for the
#### trial months. After that, find the 95th percentile of the t distribution
#### with the appropriate degrees of freedom
qt(0.95, df = degreesOfFreedom)</pre>
```

[1] 1.894579

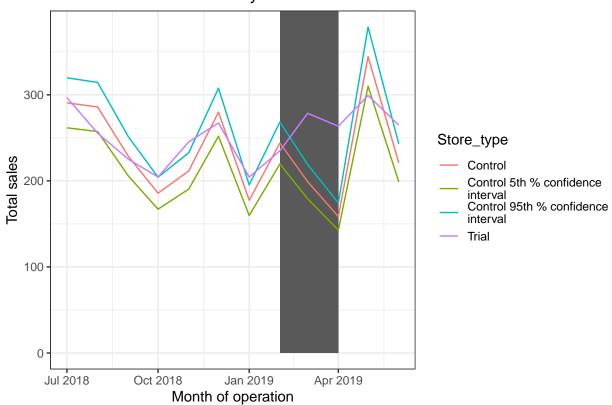

```
#### to check whether the hypothesis is statistically significant. Hint: The
#### test statistic here is (x - u)/standard deviation
percentageDiff[, `:=`(tValue, (percentageDiff - 0)/stdDev)][,
    `:=`(TransactionMonth, as.Date(paste(YEARMONTH%/%100, YEARMONTH%%100,
        1, sep = "-"), "%Y-%m-%d"))][YEARMONTH < 201905 & YEARMONTH >
    201901, .(TransactionMonth, tValue)]
```

```
## TransactionMonth tValue
## 1: 2019-02-01 1.183534
## 2: 2019-03-01 7.339116
## 3: 2019-04-01 12.476373
```

We can observe that the t-value is much larger than the 95th percentile value of the t-distribution for March and April - i.e. the increase in sales in the trial store in March and April is statistically greater than in the control store. Let's create a more visual version of this by plotting the sales of the control store, the sales of the trial stores and the 95th percentile value of sales of the control store. Let's create a more visual version of this by plotting the sales of the control store, the sales of the trial stores and the 95th percentile value of sales of the control store.

```
measureOverTimeSales <- measureOverTime</pre>
#### Trial and control store total sales Over to you! Create new variables
#### Store_type, totSales and TransactionMonth in the data table.
pastSales <- measureOverTimeSales[, `:=`(Store_type, ifelse(STORE_NBR ==</pre>
    trial_store, "Trial", ifelse(STORE_NBR == control_store, "Control",
    "Other Store")))][, `:=`(totSales, mean(totSales)), by = c("YEARMONTH",
    "Store_type")][, `:=`(TransactionMonth, as.Date(paste(YEARMONTH%/%100,
    YEARMONTH%%100, 1, sep = "-"), "%Y-%m-%d"))][Store_type %in% c("Trial",
    "Control"), ]
#### Control store 95th percentile
pastSales_Controls95 <- pastSales[Store_type == "Control", ][,</pre>
    `:=`(totSales, totSales * (1 + stdDev * 2))][, `:=`(Store_type,
    "Control 95th % confidence
interval")]
#### Control store 5th percentile
pastSales Controls5 <- pastSales[Store type == "Control", ][,</pre>
    `:=`(totSales, totSales * (1 - stdDev * 2))][, `:=`(Store_type,
    "Control 5th % confidence
```

Total sales by month

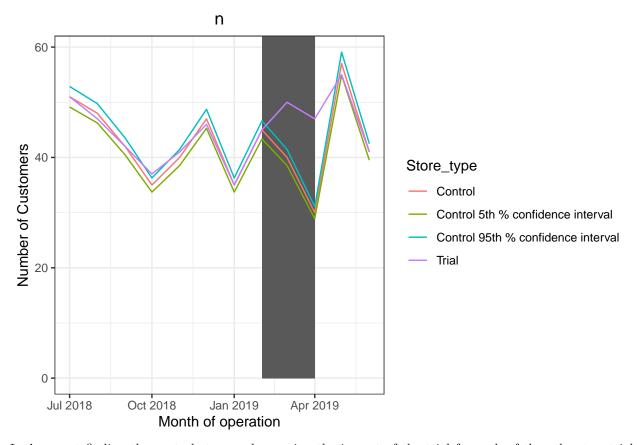

The results show that the trial in store 77 is significantly different to its control store in the trial period as the trial store performance lies outside the 5% to 95% confidence interval of the control store in two of the three trial months. Let's have a look at assessing this for number of customers as well.

```
#### This would be a repeat of the steps before for total sales Scale pre-trial
#### control customers to match pre-trial trial store customers Over to you!
#### Compute a scaling factor to align control store customer counts to our
#### trial store. Then, apply the scaling factor to control store customer
#### counts. Finally, calculate the percentage difference between scaled
#### control store customers and trial customers.
scalingFactorForControlCust <- preTrialMeasures[STORE_NBR ==
    trial_store & YEARMONTH < 201902,
    sum(nCustomers)]/preTrialMeasures[STORE_NBR ==
    control_store & YEARMONTH < 201902,
    sum(nCustomers)]</pre>
```

```
measureOverTimeCusts <- measureOverTime
scaledControlCustomers <- measureOverTimeCusts[STORE_NBR == control_store][,
   `:=`(controlCustomers, nCustomers * scalingFactorForControlCust)][,
   `:=`(Store_type, ifelse(STORE_NBR == trial_store, "Trial",
        ifelse(STORE_NBR == control_store, "Control", "Other Store")))]
percentageDiff <- merge(scaledControlCustomers[, c("YEARMONTH",
    "controlCustomers")], measureOverTimeCusts[STORE_NBR == trial_store,
    c("YEARMONTH", "nCustomers")], by = "YEARMONTH")[, `:=`(percentageDiff,
    abs(controlCustomers - nCustomers)/controlCustomers)]</pre>
```

Let's again see if the difference is significant visually!

```
#### As our null hypothesis is that the trial period is the same as the
#### pre-trial period, let's take the standard deviation based on the scaled
#### percentage difference in the pre-trial period
stdDev <- sd(percentageDiff[YEARMONTH < 201902, percentageDiff])
degreesOfFreedom <- 7</pre>
#### Trial and control store number of customers
pastCustomers <- measureOverTimeCusts[, `:=`(Store_type, ifelse(STORE_NBR ==</pre>
   trial_store, "Trial", ifelse(STORE_NBR == control_store, "Control",
    "Other Store")))][, `:=`(nCustomers, mean(nCustomers)), by = c("YEARMONTH",
    "Store_type")][, `:=`(TransactionMonth, as.Date(paste(YEARMONTH%/%100,
   YEARMONTH%%100, 1, sep = "-"), "%Y-%m-%d"))][Store_type %in% c("Trial",
    "Control"), ]
#### Control store 95th percentile
pastCustomers_Controls95 <- pastCustomers[Store_type == "Control", ][,</pre>
    := (nCustomers, nCustomers * (1 + stdDev * 2))][, := (Store type,
    "Control 95th % confidence interval")]
#### Control store 5th percentile
pastCustomers_Controls5 <- pastCustomers[Store_type == "Control", ][,</pre>
    `:=`(nCustomers, nCustomers * (1 - stdDev * 2))][, `:=`(Store_type,
    "Control 5th % confidence interval")]
trialAssessment <- rbind(pastCustomers, pastCustomers Controls95,
    pastCustomers_Controls5)
#### Over to you! Plot everything into one nice graph. Hint: geom_rect creates
#### a rectangle in the plot. Use this to highlight the trial period in our
#### graph.
ggplot(trialAssessment, aes(TransactionMonth, nCustomers,
    color = Store_type)) + geom_rect(data = trialAssessment[YEARMONTH <</pre>
   201905 & YEARMONTH > 201901, ], aes(xmin = min(TransactionMonth),
   xmax = max(TransactionMonth), ymin = 0, ymax = Inf, color = NULL),
   show.legend = FALSE) + geom_line() + labs(x = "Month of operation",
   y = "Number of Customers", title = "n")
```

Let's repeat finding the control store and assessing the impact of the trial for each of the other two trial stores.

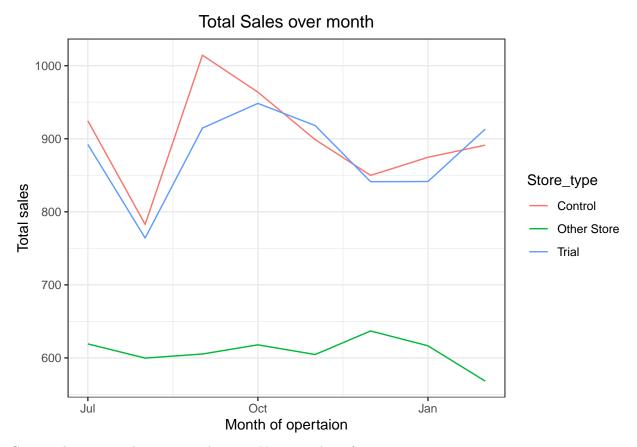

Trial store 86

```
#### Over to you! Calculate the metrics below as we did for the first trial
#### store.
measureOverTime <- data[, .(totSales = sum(TOT_SALES),</pre>
    nCustomers = uniqueN(LYLTY_CARD_NBR),
    nTxnPerCust = uniqueN(TXN_ID)/uniqueN(LYLTY_CARD_NBR),
    nChipsPerTxn = sum(PROD_QTY)/uniqueN(TXN_ID),
    avgPricePerUnit = sum(TOT_SALES)/sum(PROD_QTY)),
    by = c("YEARMONTH", "STORE_NBR")][order(YEARMONTH,
    STORE_NBR)]
#### Over to you! Use the functions we created earlier to calculate
#### correlations and magnitude for each potential control store
trial_store <- 86
corr_nSales <- calculateCorrelation(preTrialMeasures, quote(totSales),</pre>
    trial_store)
corr_nCustomers <- calculateCorrelation(preTrialMeasures, quote(nCustomers),</pre>
    trial_store)
magnitude_nSales <- calculateMagnitudeDistance(preTrialMeasures,</pre>
    quote(totSales), trial_store)
magnitude nCustomers <- calculateMagnitudeDistance(preTrialMeasures,</pre>
    quote(nCustomers), trial_store)
```

```
#### Now, create a combined score composed of correlation and magnitude
corr_weight <- 0.5</pre>
score nSales <- merge(corr nSales, magnitude nSales, by = c("Store1",
    "Store2"))[, `:=`(scoreNSales, corr_measure * 0.5 + mag_measure *
score_nCustomers <- merge(corr_nCustomers, magnitude_nCustomers,</pre>
    by = c("Store1", "Store2"))[, `:=`(scoreNCustomers, corr_measure *
    0.5 + mag_measure * 0.5
#### Finally, combine scores across the drivers using a simple average.
score_Control <- merge(score_nSales, score_nCustomers, by = c("Store1",</pre>
    "Store2"))
score_Control[, `:=`(finalControlScore, scoreNSales * 0.5 + scoreNCustomers *
    0.5)
#### Select control stores based on the highest matching store (closest to 1
#### but not the store itself, i.e. the second ranked highest store) Select
#### control store for trial store 86
control_store <- score_Control[Store1 == trial_store,</pre>
    [] [order(-finalControlScore)][2, Store2]
control_store
```

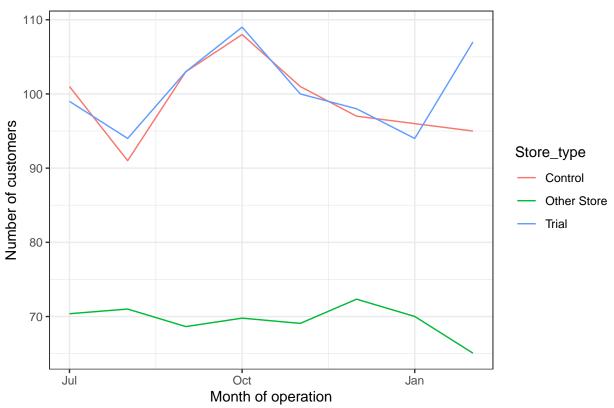

[1] 155

Looks like store 155 will be a control store for trial store 86. Again, let's check visually if the drivers are indeed similar in the period before the trial. We'll look at total sales first.

Great, sales are trending in a similar way. Next, number of customers.

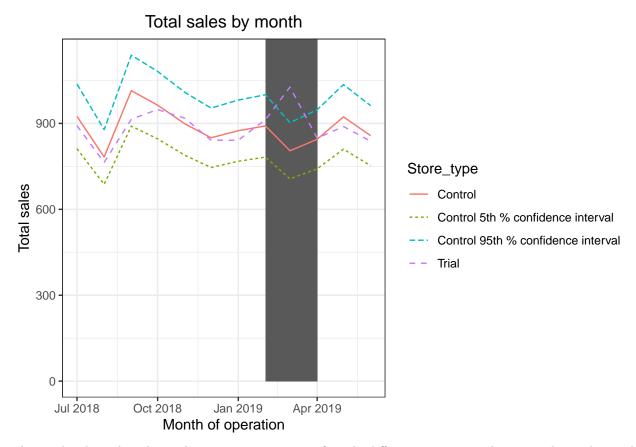

Good, the trend in number of customers is also similar. Let's now assess the impact of the trial on sales.

```
#### Scale pre-trial control sales to match pre-trial trial store sales
scalingFactorForControlSales <- preTrialMeasures[STORE_NBR ==</pre>
    trial_store & YEARMONTH < 201902,</pre>
    sum(totSales)]/preTrialMeasures[STORE_NBR ==
    control store & YEARMONTH < 201902,
    sum(totSales)]
#### Apply the scaling factor
measureOverTimeSales <- measureOverTime</pre>
scaledControlSales <- measureOverTimeSales[STORE_NBR == control_store, ][,</pre>
    `:=`(controlSales, totSales * scalingFactorForControlSales)]
#### Over to you! Calculate the percentage difference between scaled control
#### sales and trial sales Hint: When calculating percentage difference,
#### remember to use absolute difference
percentageDiff <- merge(scaledControlSales[, c("controlSales", "YEARMONTH")],</pre>
    measureOverTimeSales[, c("totSales", "YEARMONTH")], by = "YEARMONTH")[,
    `:=`(percentageDiff, abs(controlSales - totSales)/controlSales)]
#### As our null hypothesis is that the trial period is the same as the
#### pre-trial period, let's take the standard deviation based on the scaled
#### percentage difference in the pre-trial period Over to you! Calculate the
#### standard deviation of percentage differences during the pre-trial period
stdDev <- sd(percentageDiff[YEARMONTH < 201902, percentageDiff])</pre>
degreesOfFreedom <- 7</pre>
#### Trial and control store total sales Over to you! Create a table with sales
#### by store type and month. Hint: We only need data for the trial and
#### control store.
```

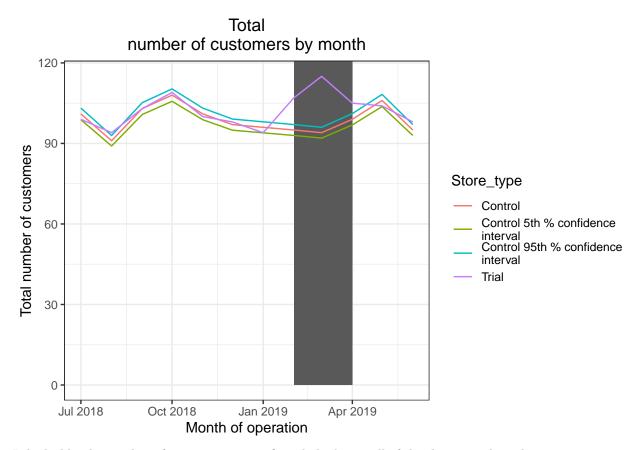

```
measureOverTimeSales <- measureOverTime</pre>
pastSales <- measureOverTimeSales[, `:=`(Store_type, ifelse(STORE_NBR ==</pre>
    trial_store, "Trial", ifelse(STORE_NBR == control_store, "Control",
    "Other Store")))][, `:=`(totSales, mean(totSales)), by = c("YEARMONTH",
    "Store_type")][, `:=`(TransactionMonth, as.Date(paste(YEARMONTH%/%100,
   YEARMONTH%%100, 1, sep = "-"), "%Y-%m-%d"))][Store_type %in% c("Trial",
    "Control"), ]
#### Over to you! Calculate the 5th and 95th percentile for control store
#### sales. Hint: The 5th and 95th percentiles can be approximated by using
#### two standard deviations away from the mean. Hint2: Recall that the
#### variable stdDev earlier calculates standard deviation in percentages, and
#### not dollar sales.
pastSales_Controls95 <- pastSales[Store_type == "Control", ][,</pre>
    `:=`(totSales, totSales * (1 + stdDev * 2))][, `:=`(Store_type,
    "Control 95th % confidence interval")]
pastSales_Controls5 <- pastSales[Store_type == "Control", ][,</pre>
    `:=`(totSales, totSales * (1 - stdDev * 2))][, `:=`(Store_type,
    "Control 5th % confidence interval")]
#### Then, create a combined table with columns from pastSales,
#### pastSales_Controls95 and pastSales_Controls5
trialAssessment <- rbind(pastSales, pastSales Controls95, pastSales Controls5)
#### Plotting these in one nice graph
ggplot(trialAssessment, aes(TransactionMonth,
   totSales, color = Store_type)) +
    geom_rect(data = trialAssessment[YEARMONTH <</pre>
        201905 & YEARMONTH > 201901,
        ], aes(xmin = min(TransactionMonth),
        xmax = max(TransactionMonth),
        ymin = 0, ymax = Inf, color = NULL),
        show.legend = FALSE) + geom_line(aes(linetype = Store_type)) +
    labs(x = "Month of operation", y = "Total sales",
        title = "Total sales by month")
```

The results show that the trial in store 86 is not significantly different to its control store in the trial period as the trial store performance lies inside the 5% to 95% confidence interval of the control store in two of the three trial months. Let's have a look at assessing this for the number of customers as well.

```
#### This would be a repeat of the steps before for total sales Scale pre-trial
#### control customers to match pre-trial trial store customers
scalingFactorForControlCust <- preTrialMeasures[STORE NBR ==</pre>
    trial_store & YEARMONTH < 201902,</pre>
    sum(nCustomers)]/preTrialMeasures[STORE_NBR ==
    control_store & YEARMONTH < 201902,</pre>
    sum(nCustomers)]
#### Apply the scaling factor
measureOverTimeCusts <- measureOverTime</pre>
scaledControlCustomers <- measureOverTimeCusts[STORE_NBR == control_store, ][, `:=`(controlCustomers,
    nCustomers * scalingFactorForControlCust)][, `:=`(Store_type, ifelse(STORE_NBR ==
    trial_store, "Trial", ifelse(STORE_NBR == control_store, "Control", "Other stores")))]
                                                                                                #### Calcul
percentageDiff <- merge(scaledControlCustomers[, c("YEARMONTH",</pre>
    "controlCustomers")], measureOverTime[STORE_NBR == trial_store,
    c("nCustomers", "YEARMONTH")], by = "YEARMONTH")[, `:=`(percentageDiff,
    abs(controlCustomers - nCustomers)/controlCustomers)]
#### As our null hypothesis is that the trial period is the same as the
#### pre-trial period, let's take the standard deviation based on the scaled
#### percentage difference in the pre-trial period
stdDev <- sd(percentageDiff[YEARMONTH < 201902, percentageDiff])</pre>
degreesOfFreedom <- 7</pre>
#### Trial and control store number of customers
```

```
pastCustomers <- measureOverTimeCusts[, `:=`(nCusts, mean(nCustomers)),</pre>
    by = c("YEARMONTH", "Store_type")][Store_type %in% c("Trial", "Control"),
#### Control store 95th percentile
pastCustomers_Controls95 <- pastCustomers[Store_type == "Control",</pre>
    ][, `:=`(nCusts, nCusts * (1 + stdDev * 2))][, `:=`(Store_type,
    "Control 95th % confidence
interval")]
#### Control store 5th percentile
pastCustomers_Controls5 <- pastCustomers[Store_type == "Control",</pre>
    ][, `:=`(nCusts, nCusts * (1 - stdDev * 2))][, `:=`(Store_type,
    "Control 5th % confidence
interval")]
trialAssessment <- rbind(pastCustomers, pastCustomers_Controls95,</pre>
    pastCustomers_Controls5)
#### Plotting these in one nice graph
ggplot(trialAssessment, aes(TransactionMonth, nCusts, color = Store_type)) +
    geom_rect(data = trialAssessment[YEARMONTH < 201905 &</pre>
        YEARMONTH > 201901, ], aes(xmin = min(TransactionMonth),
        xmax = max(TransactionMonth), ymin = 0, ymax = Inf,
        color = NULL), show.legend = FALSE) + geom_line() +
    labs(x = "Month of operation", y = "Total number of customers",
        title = "Total
number of customers by month")
```

It looks like the number of customers is significantly higher in all of the three months. This seems to suggest

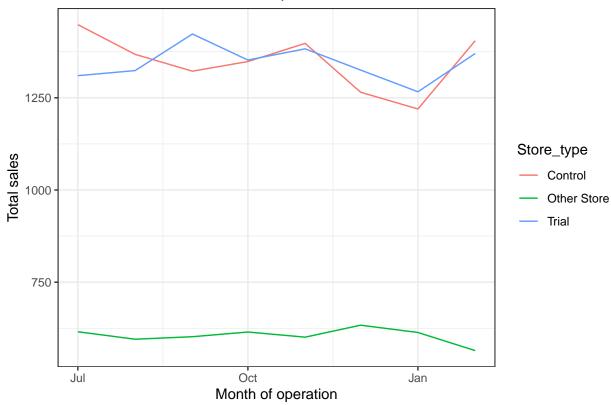

that the trial had a significant impact on increasing the number of customers in trial store 86 but as we saw, sales were not significantly higher. We should check with the Category Manager if there were special deals in the trial store that were may have resulted in lower prices, impacting the results. ## Trial store 88

```
#### All over to you now! Your manager has left for a conference call, so
#### you'll be on your own this time. Conduct the analysis on trial store 88.
measureOverTime <- data[, .(totSales = sum(TOT_SALES),</pre>
    nCustomers = uniqueN(LYLTY_CARD_NBR),
    nTxnPerCust = uniqueN(TXN ID)/uniqueN(LYLTY CARD NBR),
    nChipesPerTxn = sum(PROD_QTY)/uniqueN(TXN_ID),
    avgPricePerUnit = sum(TOT SALES)/sum(PROD QTY)),
    by = c("STORE_NBR", "YEARMONTH")][order(STORE_NBR,
    YEARMONTH)]
#### Use the functions Use the functions from earlier to calculate the
#### correlation of the sales and number of customers of each potential control
#### store to the trial store
trial_store <- 88
corr_nSales <- calculateCorrelation(preTrialMeasures, quote(totSales),</pre>
    trial_store)
corr_nCustomers <- calculateCorrelation(preTrialMeasures, quote(nCustomers),</pre>
    trial_store)
#### Use the functions from earlier to calculate the magnitude distance of the
#### sales and number of customers of each potential control store to the trial
magnitude_nSales <- calculateMagnitudeDistance(preTrialMeasures,</pre>
    quote(totSales), trial_store)
magnitude_nCustomers <- calculateMagnitudeDistance(preTrialMeasures,</pre>
    quote(nCustomers), trial_store)
#### Create a combined score composed of correlation and magnitude by merging
#### the correlations table and the magnitudes table, for each driver.
corr_weight <- 0.5</pre>
score_nSales <- merge(corr_nSales, magnitude_nSales, by = c("Store1",</pre>
    "Store2"))[, `:=`(scoreNSales, corr_measure * 0.5 + mag_measure *
    0.5)
score_nCustomers <- merge(corr_nCustomers, magnitude_nCustomers,</pre>
    by = c("Store1", "Store2"))[, `:=`(scoreNCustomers, corr_measure *
    0.5 + mag_measure * 0.5
#### Combine scores across the drivers by merging sales scores and customer
#### scores, and compute a final combined score.
score_Control <- merge(score_nSales, score_nCustomers, by = c("Store1",</pre>
    "Store2"))
score_Control[, `:=`(finalControlScore, scoreNSales * 2 + scoreNCustomers * 2)]
#### Select control stores based on the highest matching store (closest to 1
#### but not the store itself, i.e. the second ranked highest store) Select
#### control store for trial store 88
control_store <- score_Control[Store1 ==</pre>
    trial_store][order(-finalControlScore)][2,
    Store2]
control_store
```

[1] 237

We've now found store 237 to be a suitable control store for trial store 88. Again, let's check visually if the drivers are indeed similar in the period before the trial. We'll look at total sales first.

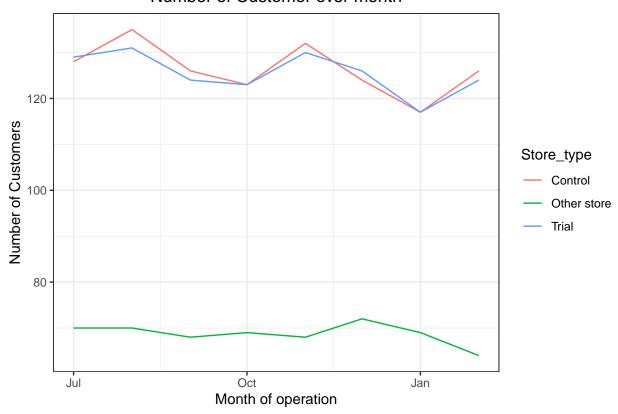

Total sales per month

Great, the trial and control stores have similar total sales. Next, number of customers.

```
ggplot(pastCustomers, aes(TransactionMonth, nCustomers, color = Store_type)) +
   geom_line() + labs(x = "Month of operation", y = "Number of Customers",
   title = "Number of Customer over month")
```

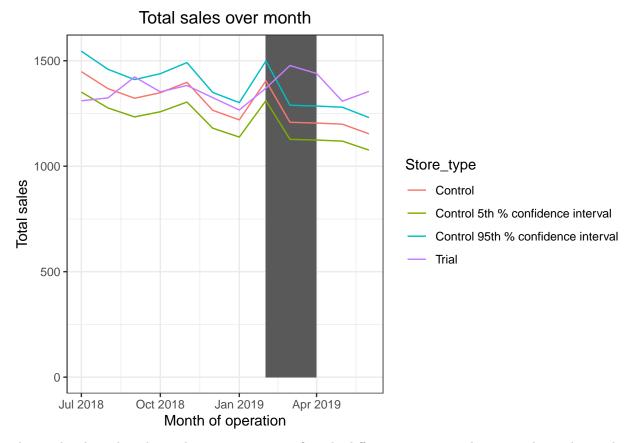

Number of Customer over month

Total number of customers of the control and trial stores are also similar. Let's now assess the impact of the trial on sales.

```
#### Scale pre-trial control store sales to match pre-trial trial store sales
scalingFactorForControlSales <- preTrialMeasures[STORE NBR ==</pre>
    trial_store & YEARMONTH < 201902,</pre>
    sum(totSales)]/preTrialMeasures[STORE_NBR ==
    control_store & YEARMONTH < 201902,</pre>
    sum(totSales)]
#### Apply the scaling factor
measureOverTimeSales <- measureOverTime</pre>
scaledControlSales <- measureOverTimeSales[STORE_NBR == control_store, ][,</pre>
    `:=`(controlSales, scalingFactorForControlSales * totSales)]
#### Calculate the absolute percentage difference between scaled control sales
#### and trial sales
percentageDiff <- merge(scaledControlSales[, c("YEARMONTH", "controlSales")],</pre>
    measureOverTimeSales[STORE NBR == trial store, c("YEARMONTH",
        "totSales")], by = "YEARMONTH")[, `:=`(percentageDiff,
    abs(controlSales - totSales)/controlSales)]
#### As our null hypothesis is that the trial period is the same as the
#### pre-trial period, let's take the standard deviation based on the scaled
#### percentage difference in the pre-trial period
```

```
stdDev <- sd(percentageDiff[YEARMONTH < 201902, percentageDiff])</pre>
degreesOfFreedom <- 7</pre>
#### Trial and control store total sales
measureOverTimeSales <- measureOverTime</pre>
pastSales <- measureOverTimeSales[, `:=`(Store_type, ifelse(STORE_NBR ==</pre>
    trial_store, "Trial", ifelse(STORE_NBR == control_store, "Control",
    "Other Store")))][, `:=`(totSales, mean(totSales)), by = c("YEARMONTH",
    "Store type")][, `:=`(TransactionMonth, as.Date(paste(YEARMONTH%/%100,
    YEARMONTH%%100, 1, sep = "-"), "%Y-%m-%d"))][Store_type %in% c("Control",
    "Trial")]
#### Control store 95th percentile
pastSales_Controls95 <- pastSales[Store_type == "Control"][,</pre>
    `:=`(totSales, totSales * (1 + stdDev * 2))][, `:=`(Store_type,
    "Control 95th % confidence interval")]
#### Control store 5th percentile
pastSales_Controls5 <- pastSales[Store_type == "Control"][,</pre>
    `:=`(totSales, totSales * (1 - stdDev * 2))][, `:=`(Store_type,
    "Control 5th % confidence interval")]
#### Combine the tables pastSales, pastSales_Controls95, pastSales_Controls5
trialAssessment <- rbind(pastSales, pastSales_Controls95, pastSales_Controls5)</pre>
#### Plot these in one nice graph
ggplot(trialAssessment, aes(TransactionMonth, totSales,
    color = Store type)) + geom rect(data = trialAssessment[YEARMONTH <</pre>
    201905 & YEARMONTH > 201901, ], aes(xmin = min(TransactionMonth),
    xmax = max(TransactionMonth), ymin = 0, ymax = Inf,
    color = NULL), show.legend = F) + geom_line() +
    labs(x = "Month of operation", y = "Total sales",
       title = "Total sales over month")
```

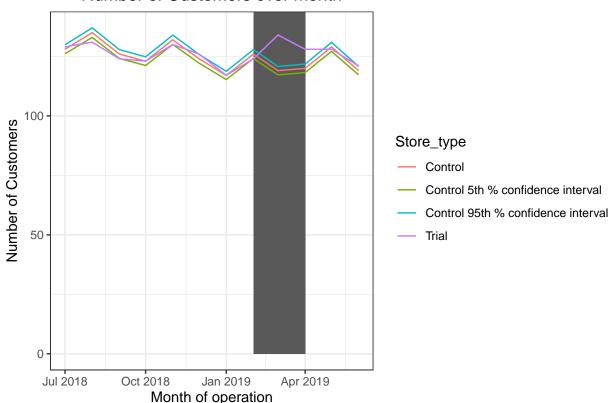

The results show that the trial in store 88 is significantly different to its control store in the trial period as the trial store performance lies outside of the 5% to 95% confidence interval of the control store in two of the three trial months. Let's have a look at assessing this for number of customers as well.

```
#### This would be a repeat of the steps before for total sales Scale pre-trial
#### control store customers to match pre-trial trial store customers
scalingFactorForControlCust <- preTrialMeasures[STORE_NBR ==</pre>
    trial_store & YEARMONTH < 201902,</pre>
    sum(nCustomers)]/preTrialMeasures[STORE NBR ==
    control store & YEARMONTH < 201902,
    sum(nCustomers)]
#### Apply the scaling factor
measureOverTimeCusts <- measureOverTime</pre>
scaledControlCustomers <- measureOverTimeCusts[STORE_NBR == control_store, ][,</pre>
    `:=`(controlCustomers, nCustomers * scalingFactorForControlCust)]
#### Calculate the absolute percentage difference between scaled control sales
#### and trial sales
percentageDiff <- merge(scaledControlCustomers[, c("YEARMONTH",</pre>
    "controlCustomers")], measureOverTimeCusts[STORE_NBR == trial_store,
    c("YEARMONTH", "nCustomers")])[, `:=`(percentageDiff, abs(controlCustomers -
    nCustomers)/controlCustomers)]
#### As our null hypothesis is that the trial period is the same as the
#### pre-trial period, let's take the standard deviation based on the scaled
#### percentage difference in the pre-trial period
stdDev <- sd(percentageDiff[YEARMONTH < 201902, percentageDiff])</pre>
degreesOfFreedom <- 7</pre>
# note that there are 8 months in the pre-trial period hence 8 - 1 = 7 degrees
```

```
# of freedom Trial and control store number of customers
pastCustomers <- measureOverTimeCusts[, `:=`(Store_type, ifelse(STORE_NBR ==</pre>
    trial store, "Trial", ifelse(STORE NBR == control store, "Control",
    "Other Store")))][, `:=`(nCustomers, mean(nCustomers)), by = c("YEARMONTH",
    "Store type")][, `:=`(TransactionMonth, as.Date(paste(YEARMONTH%/%100,
   YEARMONTH%%100, 1, sep = "-"), "%Y-%m-%d"))][Store_type %in% c("Control",
    "Trial")]
#### Control store 95th percentile
pastCustomers_Controls95 <- pastCustomers[Store_type == "Control"][,</pre>
    `:=`(nCustomers, nCustomers * (1 + stdDev * 2))][, `:=`(Store_type,
    "Control 95th % confidence interval")]
#### Control store 5th percentile
pastCustomers_Controls5 <- pastCustomers[Store_type == "Control"][,</pre>
    `:=`(nCustomers, nCustomers * (1 - stdDev * 2))][, `:=`(Store_type,
    "Control 5th % confidence interval")]
#### Combine the tables pastSales, pastSales_Controls95, pastSales_Controls5
trialAssessment <- rbind(pastCustomers, pastCustomers_Controls95,</pre>
   pastCustomers_Controls5)
#### Plotting these in one nice graph
ggplot(trialAssessment, aes(TransactionMonth, nCustomers,
    color = Store_type)) + geom_rect(data = trialAssessment[YEARMONTH <</pre>
    201905 & YEARMONTH > 201901, ], aes(xmin = min(TransactionMonth),
   xmax = max(TransactionMonth), ymin = 0, ymax = Inf, color = NULL),
   show.legend = F) + geom_line() + labs(x = "Month of operation",
   y = "Number of Customers", title = "Number of Customers over month")
```

Number of Customers over month

Total number of customers in the trial period for the trial store is significantly higher than the control store for two out of three months, which indicates a positive trial effect.

Conclusion

Good work! We've found control stores 233, 155, 237 for trial stores 77, 86 and 88 respectively. The results for trial stores 77 and 88 during the trial period show a significant difference in at least two of the three trial months but this is not the case for trial store 86. We can check with the client if the implementation of the trial was different in trial store 86 but overall, the trial shows a significant increase in sales. Now that we have finished our analysis, we can prepare our presentation to the Category Manager.
